

Product Idea

“ProofOS”

THE REPUTATION AND CONTRIBUTION LAYER FOR BUILDERS

One-line vision

“A universal proof-of-work profile for developers, contributors, creators, and web3 builders.”

People own their contribution history and reputation across the internet.

Core Problem

Today reputation is fragmented:

- GitHub shows code
- LinkedIn shows jobs
- Discord shows community activity
- wallets show onchain activity
- hackathons show submissions

There is NO unified proof-of-contribution system.

This creates:

- fake experts
 - hiring difficulty
 - reputation fragmentation
 - no portable credibility
-

Solution

ProofOS creates:

- a public contribution graph
- verifiable reputation
- proof-of-work identity
- developer trust scoring

using:

- wallet activity
 - GitHub activity
 - hackathon participation
 - endorsements
 - project history
 - community proofs
-

Target Users

PHASE 1

- web3 developers
 - hackathon builders
 - indie hackers
 - DAO contributors
-

PHASE 2

- startups
 - recruiters
 - DAOs
 - grant programs
-

PHASE 3

- all internet creators/builders
 - AI agents
 - freelancer ecosystems
-

Why Users Care

Users want:

- credibility
 - public portfolio
 - hiring proof
 - trust
 - reputation portability
-

Why Companies Care

Companies want:

- contributor verification
 - better hiring signals
 - trust scoring
 - anti-sybil systems
-

Why Arkiv Fits

Arkiv is used for:

- immutable contribution records
- endorsements
- reputation entities
- relationship graphs
- proof history

Arkiv becomes:

 the public trust layer.

Core Features

1. Universal Builder Profile

Example:

Shows:

- wallet activity
 - GitHub contributions
 - projects
 - hackathons
 - endorsements
 - badges
 - trust score
-

2. Contribution Proofs

Users can add:

- project contributions
- design work
- code commits
- hackathon entries
- DAO participation

Each stored as Arkiv entities.

3. Endorsements

Other builders endorse:

- skills
- collaboration
- trustworthiness

Example:

“Worked with Rohan on Arkiv hackathon.”

4. Reputation Engine

Score based on:

- verified contributions
 - endorsements
 - project quality
 - consistency
 - scam reports
 - community trust
-

5. Public API

This is the real business layer.

Apps can fetch:

- contributor scores
 - trust signals
 - proof verification
 - project history
-

API Endpoints

GET REPUTATION

GET /api/reputation/:wallet

GET CONTRIBUTIONS

GET /api/contributions/:wallet

VERIFY USER

POST /api/verify

GET ENDORSEMENTS

GET /api/endorsements/:wallet

API Customers

DAOS

Use for contributor verification.

HIRING PLATFORMS

Use for candidate scoring.

HACKATHONS

Use for participant credibility.

WEB3 STARTUPS

Use for trust systems.

GRANT PROGRAMS

Use to verify builders.

Business Model

1. API SaaS (main revenue)

Pricing:

Tier	Price
Free	1k requests
Pro	\$49/mo
Team	\$299/mo
Enterprise	custom

2. Premium Profiles

Users pay for:

- advanced analytics
- verified badges
- AI portfolio generation
- featured profiles

3. Talent Discovery

Recruiters pay for:

- contributor search
- reputation filters
- sourcing tools

Long-Term Vision

ProofOS becomes:

“The internet trust layer for builders.”

Like:

- LinkedIn reputation
- GitHub activity
- wallet trust
- AI-era proof-of-work

combined.

Tech Stack

FRONTEND

- Next.js
 - Tailwind
 - shadcn/ui
-

BACKEND

- Node.js
 - Express
-

DATABASE

- PostgreSQL
 - Redis
-

BLOCKCHAIN/IDENTITY APIS

- GitHub API
 - ENS
 - Alchemy
 - wallet APIs
-

Arkiv Usage

ENTITY TYPES

CONTRIBUTION ENTITY

```
{  
  "type": "contribution",  
  "project": "Proof0S",  
  "role": "frontend",  
  "github": "repo-link"  
}
```

ENDORSEMENT ENTITY

```
{  
  "from": "0xabc",
```

```
"to": "0xyz",  
"message": "Great Solidity dev"  
}
```

BADGE ENTITY

```
{  
  "badge": "Hackathon Winner",  
  "issuedBy": "Arkiv"  
}
```

Go-To-Market Strategy

PHASE 1

Target:

- hackathons
 - Twitter/X builders
 - web3 communities
-

PHASE 2

Launch:

- public profiles
 - leaderboards
 - builder discovery
-

PHASE 3

Push API integrations.

Why This Can Scale

Because reputation compounds.

More users →

more endorsements →

better trust graph →

better API value →

more integrations.

Network effects.

Biggest Risks

1. FAKE ENDORSEMENTS

Need anti-spam mechanisms.

2. COLD START

Need initial community.

3. REPUTATION MANIPULATION

Need scoring safeguards.

Why This Is Strong

- understandable
 - API-friendly
 - scalable
 - Arkiv-native
 - network effects
 - real problem
 - B2B potential
 - community-driven
-

IMPORTANT

Do NOT position it as:

“web3 social reputation app.”

Bad positioning.

Position it as:

“Proof-of-work identity infrastructure.”

Much stronger.
